

GET THE MERCURY OUT

Strategic Mercury Cleanup Targets

UPLAND SOURCES

such as legacy gold mines

Upland sources need to be identified, assessed, prioritized and cleaned up.

The Sierra Fund is pioneering methods of assessment and remediation of legacy mercury pollution at **Malakoff Diggins State Historic Park**, aimed at understanding how to clean up or divert water around these kinds of sources to minimize mercury transport and bioaccumulation downstream. This collaborative project is conducted with State Parks and other state and federal agencies, with seed funding provided by the Sierra Nevada Conservancy.

Methylmercury is the highest priority toxic bioaccumulative contaminant in California (Davis, 2012).*

RESERVOIRS

built downstream of legacy mines, where mercury-laden sediments accumulate

The Nevada Irrigation District's pilot project at **Combie Reservoir**, in collaboration with US Geological Survey and others, is the first effort ever undertaken to determine if removing mercury-contaminated sediment as part of dredging to maintain reservoir capacity can reduce the amount of mercury in reservoir releases. This project promotes water supply reliability and sustainability by maintaining reservoir capacity.

For about 200 reservoirs in California, estimated sediment deposition of 2.1 billion cubic meters (1.7 million acre-feet) has cut their storage capacity in half. (Minear and Kondolf, 2009).*

More than 96% of the total mercury loading to the Bay-Delta comes from the streams and rivers of the Sierra Nevada and the Inner Coast Range (Wood et al., 2010).*

SOIL EROSION

adding mercury to streams and rivers

Projects that focus on reducing soil erosion into **Cache Creek, Putah Creek**, and other Inner Coast Range water bodies can abate the mercury release as well as sediment contamination downstream.

UPLAND SOURCES

such as legacy mercury mines

Unlike legacy gold mines that can be cleaned up, mercury mines require continuous treatment because the mercury deposit is on site. These mines need to be identified, assessed, prioritized, and cleaned up.

Tuleyome's project to remediate legacy mercury mines in Napa County is an example that demonstrates an effective role for non-profit organizations. Other recent examples of this type of cleanup are the **Abbott-Turkey Run Mine** in Lake County and the **BLM Rathburn-Petray Mine** in Colusa County.

SOLUTION

Funding to assess, design and implement these sorts of pilot projects must be included in the next water bond.

Proposed language for inclusion in a new water bond:

“ **Delta Sustainability:** Funding for pilot projects that reduce discharge of mercury into the Delta from upstream legacy gold and mercury mines. ”

* All facts provided in this brochure are fully referenced in the associated fact sheet, available at www.reclaimingthesierra.org

MERCURY-CONTAMINATED SEDIMENT

reduces reservoir storage capacity. Millions of gallons of mercury were poured into mining sluices and tunnels and lost to the streams and rivers. As a result, mercury-contaminated sediment continues to move downstream with every storm event.

PUBLIC HEALTH

is threatened by mercury from legacy mines. When the price of gold fell, mines were abandoned without any effort to clean them up. A century later toxic mercury is still leaking into the state's water system. Public health officials in California are increasingly concerned about the amount of mercury in the fish of the state and the danger posed by eating fish caught in the San Francisco Bay-Delta and in rivers and reservoirs in the Sierra Nevada and Inner Coast Range. **Mercury exposure, especially during pregnancy or as a young child, can cause devastating and permanent health effects.**

GET THE MERCURY OUT

a campaign to increase public investment in restoring California's watersheds

By reclaiming legacy mines, California will:

- Maintain reservoir capacity
- Protect public health
- Reduce mercury contamination of the San Francisco Bay-Delta

As part of the "rush for gold in California" 150 years ago,

huge machines tore apart mountains looking for gold. These disturbed and polluted mountain remnants tumbled down from the Sierra Nevada as a thick wall of mud flooding the valleys and the San Francisco Bay-Delta.

MERCURY

was used extensively during the Gold Rush in the Sierra Nevada in both hard rock and hydraulic mining. Mercury was mined in the Coast Range (cinnabar deposits), transported to the Sierra and used as quicksilver to extract gold.
